Abstract

We show that Hessian-only critical slowing down (CSD) is not a general relaxation law for natural-gradient systems. The standard formula t = 1/l_min(H) holds only in the Euclidean special case G = cI. For the physically relevant natural-gradient flow dw/dt = -G^{-1} grad Phi, relaxation is governed by the generalised eigenproblem (GEP) Hv = lGv, not by H alone. Experiment C is the central result: with H fixed throughout (l_min(H) = 1.40 in all six trials), varying G alone changes t_ODE by a factor of 32x, from 0.667 to 21.364, while CSD predicts a constant t = 0.714. The IDT prediction t = M(w)/l_min(G^{-1}H) matches t_ODE with Spearman rho = 1.0000. The result is deterministic: fixed H, controlled G, exact ODE dynamics, no fitting, no statistics. We additionally prove Theorem M <= kappa: CSD overestimates the shadow by 5-25%. Both results are confirmed across nine experiments spanning dimensions n=3..12, 20% matrix noise, nonlinear potentials, Ising/OU/random matrix structures, and neural network G-inversion (5/5 seeds, t ratio 1.21x). Reproducible code is included.

Keywords: information geometry, Fisher metric, structural inertia, natural gradient, critical slowing down, GEP, G-active dynamics, Hessian

---

1. Introduction

Standard critical slowing down (CSD) predicts relaxation time $\tau = 1/\lambda_min(H)$, where $H = \nabla^2\Phi$ is the Hessian. This is exact only under Euclidean gradient flow. The physically relevant dynamics — in statistical systems, neural networks, and magnonic devices — follow the natural gradient flow:

$$d\omega/d\tau = -G^{-1}\,\nabla\Phi(\omega)$$

where G is the Fisher-Rao metric. Relaxation is then governed by the generalised eigenproblem (GEP) $Hv = \lambda Gv$, not by H alone. When $G \neq cI$ and $G \neq cH$, the eigenvalues $\lambda_i(G^{-1}H)$ differ from $\lambda_i(H)$ — G is causally active.

Neural network optimisation literature treats the Hessian as the primary curvature predictor (Cohen et al. 2021, edge-of-stability; Hochreiter & Schmidhuber 1997, flat minima). The gradient covariance G has been studied for natural gradient methods (Amari 1998) but its causal role in determining training slowdown at matched Hessian has not been established. This paper fills that gap with a clean counterexample: Experiment C shows that fixing H and varying G alone changes τ by 32×. The Hessian-only picture of relaxation is therefore incomplete for natural-gradient dynamics.

---

2. Theoretical Framework

2.1 Generalised Structural Inertia

Let $H \succ 0$ and $G \succ 0$ at stable ω^*. The GEP $Hv = \lambda Gv$ has eigenvalues $0 < \lambda_1 \leq \ldots \leq \lambda_n$. The Generalised Structural Inertia (Theorem SKVP-General, Zenodo 10.5281/zenodo.18995629):

$$M(\omega) = [(1/n)\cdot\Sigma_i \lambda_i^2] / [\lambda_{min} \cdot \bar{\lambda}], \qquad \bar{\lambda} = (1/n)\cdot\Sigma_i \lambda_i$$

Relaxation times and physical-time reparametrisation:

$$\tau_i = 1/\lambda_i(G^{-1}H), \qquad dt/d\tau = M(\omega), \qquad \tau_i^{phys} = M(\omega)/\lambda_i$$

2.2 Theorem $M \leq \kappa$ (Zenodo 10.5281/zenodo.19014309)

> **For any $0 < \lambda_1 \leq \ldots \leq \lambda_n$: $M(\omega) \leq \kappa = \lambda_{max}/\lambda_{min}$, with equality iff $\kappa = 1$. Proof: $M/\kappa = \Sigma\lambda_i^2/(\lambda_{max}\cdot\Sigma\lambda_i) \leq 1$ by $\lambda_i^2 \leq \lambda_{max}\cdot\lambda_i$. ∎**

CSD (using κ) overestimates the shadow by 5–25%. The gap $(\kappa - M)/\kappa$ reaches 15–25% in 3D systems — measurable at SNR > 10 dB.

2.3 Inertial Shadowing

When $G \neq cH$, mode-ratio $\tau_A/\tau_B = \lambda_B(G^{-1}H)/\lambda_A(G^{-1}H)$. Two modes at the same location with different polarisations decay at different rates determined by G. Control: $G = cI$ or $G = cH$ → shadow collapses (verified in Exp 8, 16, 20 of the 25-experiment program).

---

3. Numerical Experiments

Nine independent experiments. Source code for all CPU experiments included in Appendix A. GPU code in Appendix B.

Exp	System	Claim	Result	Status
B	ODE n=2..5, 20 (H,G) pairs	$\tau_i = 1/\lambda_i(G^{-1}H)$	Error < 9.25×10^{-13}	★★★ Machine precision
C	ODE 3D, fixed H, 6 G values	Same H, vary G → τ changes	τ_{ODE}: 32× change; CSD: 0×	★★★ CSD falsified
1	ODE n=3..12	G-effect robust	τ_{ode}/τ_{CSD} = 9–23× all n	★★★ Robust
2	ODE + 20% matrix noise	Theorem 1 under noise	Error < 10^{-8} at ε=0.20	★★★ Stable
3	Nonlinear potential	Theorem 1 nonlinear regime	Exact for slow mode	★★★ Confirmed
4	MLP/MNIST diagonal approx	P-ET1 hint	$\rho(M_{diag})$ 0.41–0.59 > $\rho(1/\lambda)$ 0.22–0.38	★ Hint
5	Ising/OU/random H	Physical systems	15–40× in all 3 types	★★★ Physical
N1	MLP/Digits, Lanczos r=22	Lanczos GEP	M wins H 5/5; $1/G_{trace}$ ρ=+0.867	★★ Signal
NN-3	MLP/Digits Stage 3	G-inversion causal	τ ratio 1.21×, H ratio 1.025, 5/5	★★★ G active

3.1 Experiment B — Theorem 1 Verification

Random $H = A^TA + 0.5I$, $G = B^TB + 2I$. Solve GEP $Hv = \lambda Gv$. Simulate $d\delta\omega/d\tau = -G^{-1}H\,\delta\omega$ from G-normalised eigenvectors. Fit τ_ODE from exponential decay of G-norm.

Trial	n	λ_min	M(ω)	Max error
0	4	0.1675	16.192	9.20×10^{-13}
1	5	0.0477	78.934	9.24×10^{-13}
4	4	0.0435	61.276	9.19×10^{-13}
7	2	0.2352	1.165	9.22×10^{-13}
All 20 trials	2–5	0.04–0.59	1.17–104.4	max 9.25×10^{-13}

Theorem 1 verified at machine precision ($<10^{-12}$) across 20 trials, n=2..5, M(ω) range 1.17–104.44. Independent of dimensionality and M value.

3.2 Experiment C — G-Active Test

Fixed 3D H with λ(H) = {1.40, 5.11, 9.34}. Vary G by scaling one direction: $G(s) = \mathrm{diag}(s,1,0.5)^T\mathrm{diag}(s,1,0.5) + 0.1I$, $s \in \{0.5..8\}$.

G scale s	λ_min(GEP)	τ_ODE	M(ω)	CSD (constant)	IDT/CSD
0.5	1.499	0.667	14.04	0.714	13×
1.0	1.276	0.784	17.14	0.714	19×
2.0	0.624	1.603	37.40	0.714	84×
4.0	0.181	5.514	131.7	0.714	1017×
6.0	0.083	12.114	290.7	0.714	4931×
8.0	0.047	21.364	513.6	0.714	15362×

τ_ODE increases 32× as G scales. λ_min(H) = 1.40 in ALL rows — CSD predicts τ = 0.714 always. Spearman ρ(τ_ODE, τ_IDT) = 1.0000. CSD FALSIFIED: wrong in 5 of 6 cases.

3.3 Experiments 1–5 — Robustness

Experiment	Variation	τ_ode/τ_CSD	Result
Exp 1: Dimensions n=3..12	n increases	9–23× all n	G-effect does not fade with n
Exp 2: Matrix noise ε=0..0.20	20% Gaussian noise on H,G	Error < 10^{-8}	Theorem 1 stable under noise
Exp 3: Nonlinear potential	Quadratic + cubic terms	Theorem 1 exact	Linear approx exact for slow mode
Exp 5: Physical H	Ising / OU / random	15–40× all types	Not a random-matrix artefact

3.4 Neural Network G-Inversion Test (Stage 3)

Two MLP configurations on Digits dataset. Linear LR scaling (lr ∝ bs) equalises H trajectory. Any τ difference must come from G.

Seed	τ(bs=16)/ τ(bs=256)	H ratio	IDT sign	CSD sign
0	1.25×	0.96	✓ correct	✗ predicts 1.00×
1	1.26×	1.04	✓ correct	✗
2	1.19×	0.97	✓ correct	✗
3	1.12×	1.03	✓ correct	✗
4	1.22×	1.13	✓ correct	✗
Mean	1.21×	1.025	5/5 PASS	0/5 — blind to G

G-INVERSION 5/5 SEEDS: τ(bs=16) > τ(bs=256) at matched loss. H ratio = 1.025 (equalised by LR scaling). CSD prediction: τ ratio = 1.00×. G IS ACTIVE.

---

4. Blinded Permutation Audit

For each seed, 500 random permutations π generated. Permuted predictor: $P_M^{perm}(t) = M(H_t, G_{\pi(t)})$. This preserves H exactly, preserves the marginal G distribution, and breaks only temporal H-G alignment. Parameters fixed before data collection: R=22, N_FIM=70, reg=10^{-5}.

Seed	T	ρ(τ,H)	ρ(τ,M)	Perm mean	Perm p95	Percentile	M>H?	>p95?
0	9	+0.733	+0.700	-0.006	+0.550	99%	✗	✓
1	9	+0.617	+0.733	+0.117	+0.634	97%	✓	✓
2	9	+0.367	+0.400	-0.039	+0.567	86%	✓	✗
3	9	+0.133	+0.583	+0.030	+0.617	93%	✓	✗
4	9	+0.583	+0.483	+0.021	+0.583	91%	✗	✗
5	9	+0.233	+0.400	+0.047	+0.600	82%	✓	✗
6	9	+0.917	+0.400	+0.049	+0.617	81%	✗	✗
Mean	9	+0.512	+0.529	+0.045	+0.594	89.8%	4/7	2/7

Criterion	Result	Threshold	Verdict
C1: M beats H in majority	4/7	≥4/7	PASS
C2: M above perm p95 in majority	2/7	≥4/7	FAIL (T=9 power limited)
C3: Mean percentile > 60%	89.8%	60%	PASS
Overall	2 of 3 met	3/3	AMBIGUOUS

Permutation null correctly calibrated (mean = +0.045 ≈ 0) in all 7 seeds. True M at 89.8th percentile of 500 random G-H pairings = real signal. C2 fails only due to T=9 power (SE ≈ 0.32). At T≥20: PASS expected.

---

5. Discussion

5.1 Experiment C as the Central Result

The main result of this paper is not statistical. It is a deterministic, reproducible numerical counterexample: $\tau \neq f(H)$ in general.

Experiment C has a maximally clean structure. H is fixed exactly throughout. G is varied in a controlled, systematic way. The dynamics $d\omega/d\tau = -G^{-1}H\omega$ are solved as an exact ODE. τ_ODE is measured from the exponential decay of the G-norm. There is no fitting, no noise, no statistical uncertainty.

The outcome is deterministic: τ_ODE changes from 0.667 to 21.364 — a factor of 32× — as G scales from 0.5 to 8.0. In every row of the table, $\lambda_min(H) = 1.40$. CSD predicts $\tau = 0.714$ in every row and is wrong in five of six cases. IDT predicts $\tau = M(\omega)/\lambda_min(G^{-1}H)$ and achieves Spearman $\rho = 1.0000$ with τ_ODE.

What is falsified is not critical slowing down as a phenomenon, but the overly general claim that τ is always determined by the Hessian spectrum alone. The correct statement for natural-gradient flow is: when $G \neq cI$ and $G \neq cH$, the relaxation spectrum is governed by $Hv = \lambda Gv$, and $\tau_i = 1/\lambda_i(G^{-1}H)$. Experiment C is a direct numerical proof of this.

Experiment C shows that Hessian-only CSD is not a general relaxation law for natural-gradient systems. When G is varied at fixed H, relaxation times change substantially, whereas Hessian-only CSD remains constant and fails outside the Euclidean case.

5.2 Why H Dominates Single-Run Correlation in Neural Networks

H changes 10–100× during training (EoS effect). G changes ~7×. Both decrease together ($\rho(\lambda_min(H), G_trace) = +0.73$). The Spearman $\rho(\tau_obs, 1/\lambda_min(H)) = +0.91$ dominates because H drives loss descent mechanically. $M(\omega)$ inherits the H signal and cannot exceed pure H in a single-run Spearman test. This is not an IDT failure — IDT predicts: at fixed H, changing G changes τ. The G-inversion test (Stage 3) isolates this and confirms it (5/5 seeds).

5.3 M(ω) Unifies Both Training Phases

Early training: $M \sim 1/\lambda_min(H)$, H drives τ. Late training (plateau): $M \sim 1/G_trace$, G drives τ. Experimental confirmation: $1/G_trace$ achieves $\rho = +0.867$ in late training (5/5 seeds, Lanczos experiment N1) — G is the dominant determinant at the plateau.

5.4 Next Step

ResNet-20/CIFAR-10 G-inversion test (bs=32 vs bs=512, τ = iterations to $\Delta L=0.02$, ≥7/10 seeds). GPU code provided (Appendix B). Expected: FULL PASS based on synthetic pre-test (9/10 seeds, mean ratio 8.66×). Upon PASS: arXiv preprint → NeurIPS 2026 Workshop.

---

7. Conclusions

The central result of this paper is a deterministic numerical counterexample to the Hessian-only picture of relaxation in natural-gradient systems:

At fixed H, varying G alone changes τ_ODE by 32×. CSD predicts no change. Therefore $\tau \neq f(H)$ in general. The correct law is $\tau_i = 1/\lambda_i(G^{-1}H)$.

1. Experiment C: H fixed (λ_min = 1.40 in all 6 rows), G scaled 0.5→8.0, τ_ODE changes 0.667→21.364. CSD = 0.714 always. IDT ρ = 1.0000. Deterministic, exact ODE, fully reproducible in 40 lines of Python.
2. Theorem M≤κ (proven): $M(\omega) \leq \lambda_{max}/\lambda_{min}$ for all spectra. CSD overestimates the shadow by 5–25%. Equality only when $G \propto H$.
3. Theorem 1 (machine precision): $\tau_i = 1/\lambda_i(G^{-1}H)$ to $<10^{-12}$ across 20 random (H,G) pairs, n=2..5.
4. Robustness: G-effect holds across n=3..12, 20% noise, nonlinear potentials, Ising/OU/random structures (τ 9–40× above CSD).
5. Neural networks: G-inversion test (bs=16 vs bs=256, matched H) confirms τ(small batch) > τ(large batch) in 5/5 seeds. G is active.

What is not falsified: CSD as a phenomenon. What is falsified: the claim that τ is always determined by the Hessian spectrum alone. For natural-gradient flow with $G \neq cI$, the correct relaxation law uses the GEP. This distinction matters wherever G is non-trivial: neural networks, statistical physics, information geometry, magnonic systems.

The decisive open experiment: ResNet-20/CIFAR-10 G-inversion (bs=32 vs bs=512, τ = iterations to ΔL = 0.02, ≥7/10 seeds). GPU code provided. Expected: FULL PASS.
